Excerpt: . . . each type of cloud is lower in winter than summer, lower over humid than over desert regions, lower over oceans than continents, and lower with increase of latitude. The table on this page, copied from Hanns Lehrbuch der Meteorologie, gives the average summer and winter heights of clouds at places of widely different latitudes. Levels of Maximum Cloudiness. --When the frequency of clouds is tabulated with reference to elevation, maxima and minima are found with the layers to which they obtain growing thicker with decrease of latitude. This phenomenon, as a whole, is interesting, but it will be necessary, in discussing it, to consider the different levels separately, since each has its own explanation. Fog Level. --As already explained, fogs, whether caused by radiation or advection, are surface phenomena, seldom more than 100 to 200 metres thick. Hence the surface of the earth, because of the fogs that form upon it, is itself a level of maximum condensation or maximum cloudiness. Cumulus Level. --Since the cumulus and the cyclone nimbus both are due to vertical convection--the first thermal, the second forced--it is obvious that the base of each occurs approximately at the saturation level; that is, the level at which a mass of air rising from the surface will have cooled to its dew-point. Clearly, too, clouds cannot form at a lower level, the air there being unsaturated, and even if drifted in they would evaporate. Further, ordinary thermal convection usually does not extend...
